

1. Business Problem

1.1 Problem Description

Netflix is all about connecting people to the movies they love. To help customers find those movies, they developed world-class movie recommendation system: CinematchSM. Its job is to predict whether someone will enjoy a movie based on how much they liked or disliked other movies. Netflix use those predictions to make personal movie recommendations based on each customer's unique tastes. And while **Cinematch** is doing pretty well, it can always be made better.

Now there are a lot of interesting alternative approaches to how Cinematch works that netflix haven't tried. Some are described in the literature, some aren't. We're curious whether any of these can beat Cinematch by making better predictions. Because, frankly, if there is a much better approach it could make a big difference to our customers and our business.

Credits: https://www.netflixprize.com/rules.html

1.2 Problem Statement

Netflix provided a lot of anonymous rating data, and a prediction accuracy bar that is 10% better than what Cinematch can do on the same training data set. (Accuracy is a measurement of how closely predicted ratings of movies match subsequent actual ratings.)

1.4 Real world/Business Objectives and constraints

Objectives:

- 1. Predict the rating that a user would give to a movie that he ahs not yet rated.
- 2. Minimize the difference between predicted and actual rating (RMSE and MAPE)

Constraints:

1. Some form of interpretability.

2. Machine Learning Problem

2.1 Data

2.1.1 Data Overview

Get the data from : https://www.kaggle.com/netflix-inc/netflix-prize-data/data

Data files:

- combined_data_1.txt
- combined_data_2.txt
- · combined data 3.txt
- combined_data_4.txt
- movie_titles.csv

The first line of each file [combined_data_1.txt, combined_data_2.txt, combined_data_3.txt, combined_data_4.txt] contains the movie id followed by a colon. Each subsequent line in the file corresponds to a rating from a customer and its date in the following format:

CustomerID, Rating, Date

MovieIDs range from 1 to 17770 sequentially. CustomerIDs range from 1 to 2649429, with gaps. There are 480189 users. Ratings are on a five star (integral) scale from 1 to 5. Dates have the format YYYY-MM-DD.

2.1.2 Example Data point

2.2 Mapping the real world problem to a Machine Learning Problem

2.2.1 Type of Machine Learning Problem

For a given movie and user we need to predict the rating would be given by him/her to the movie.

The given problem is a Recommendation problem It can also seen as a Regression problem

2.2.2 Performance metric

- Mean Absolute Percentage Error: https://en.wikipedia.org/wiki/Mean absolute percentage error
- Root Mean Square Error: https://en.wikipedia.org/wiki/Root-mean-square deviation

2.2.3 Machine Learning Objective and Constraints

- 1. Minimize RMSE.
- 2. Try to provide some interpretability.

```

3.3.8 Cold Start problem

3.3.8.1 Cold Start problem with Users

We might have to handle **new users** (75148) who didn't appear in train data.

No of Users that didn't appear in train data: 75148(15.65 %)

3.3.8.2 Cold Start problem with Movies

We might have to handle 346 movies (small comparatively) in test data

No of Movies that didn't appear in train data: 346(1.95 %)

3.4 Computing Similarity matrices

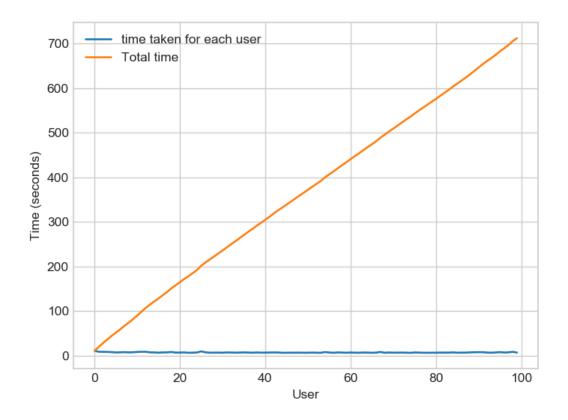

3.4.1 Computing User-User Similarity matrix

- 1. Calculating User User Similarity_Matrix is **not very easy**(*unless you have huge Computing Power and lots of time*) because of number of. usersbeing lare.
 - You can try if you want to. Your system could crash or the program stops with Memory Error

3.4.1.1 Trying with all dimensions (17k dimensions per user)

```
In [22]: from sklearn.metrics.pairwise import cosine similarity
         def compute user similarity(sparse matrix, compute for few=False, top = 100, v
         erbose=False, verb for n rows = 20,
                                      draw_time_taken=True):
             no_of_users, _ = sparse_matrix.shape
             # get the indices of non zero rows(users) from our sparse matrix
             row ind, col ind = sparse matrix.nonzero()
             row ind = sorted(set(row ind)) # we don't have to
             time taken = list() # time taken for finding similar users for an user..
             # we create rows, cols, and data lists.., which can be used to create spar
         se matrices
             rows, cols, data = list(), list(), list()
             if verbose: print("Computing top",top,"similarities for each user..")
             start = datetime.now()
             temp = 0
             for row in row ind[:top] if compute for few else row ind:

                 plt.legend(loc='best')
                 plt.xlabel('User')
                 plt.ylabel('Time (seconds)')
                 plt.show()
```

```
computing done for 20 users [ time elapsed : 0:02:37.853407 ] computing done for 40 users [ time elapsed : 0:04:58.198449 ] computing done for 60 users [ time elapsed : 0:07:13.983985 ] computing done for 80 users [ time elapsed : 0:09:29.641494 ] computing done for 100 users [ time elapsed : 0:11:52.529683 ] Creating Sparse matrix from the computed similarities
```

Time taken: 0:12:12.785933

3.4.1.2 Trying with reduced dimensions (Using TruncatedSVD for dimensionality reduction of user vector)

- We have 405,041 users in out training set and computing similarities between them..(17K dimensional vector..) is time consuming..
- From above plot, It took roughly 8.88 sec for computing similar users for one user
- We have 405,041 users with us in training set.
- $405041 \times 8.88 = 3596764.08 \, \text{sec} = 59946.068 \, \text{min} = 999.101133333 \, \text{hours} = 41.629213889 \, \text{day}$
 - Even if we run on 4 cores parallelly (a typical system now a days), It will still take almost 10 and 1/2 days.

IDEA: Instead, we will try to reduce the dimentsions using SVD, so that it might speed up the process...

```
In []: from datetime import datetime
    from sklearn.decomposition import TruncatedSVD

    start = datetime.now()

# initilaize the algorithm with some parameters..

# All of them are default except n_components. n_itr is for Randomized SVD sol
    ver.

netflix_svd = TruncatedSVD(n_components=500, algorithm='randomized', random_st
    ate=15)
    trunc_svd = netflix_svd.fit_transform(train_sparse_matrix)

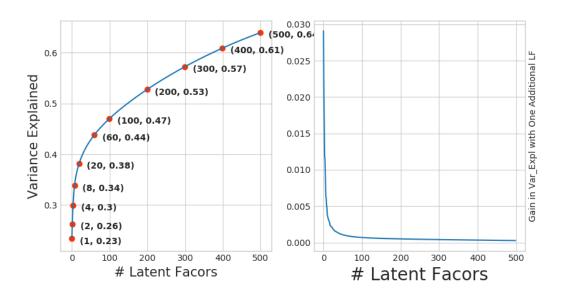

print(datetime.now()-start)
```

Here,

- $\sum \longleftarrow$ (netflix_svd.singular_values_)
- $\bigvee^T \longleftarrow$ (netflix_svd.components_)
- Usinot returned. instead **Projection_of_X** onto the new vectorspace is returned.
- It uses randomized svd internally, which returns All 3 of them saperately. Use that instead..

```
In [0]: expl_var = np.cumsum(netflix_svd.explained_variance_ratio_)
```

```
In [0]: | fig, (ax1, ax2) = plt.subplots(nrows=1, ncols=2, figsize=plt.figaspect(.5))
        ax1.set ylabel("Variance Explained", fontsize=15)
        ax1.set xlabel("# Latent Facors", fontsize=15)
        ax1.plot(expl var)
        # annote some (latentfactors, expl_var) to make it clear
        ind = [1, 2,4,8,20, 60, 100, 200, 300, 400, 500]
        ax1.scatter(x = [i-1 for i in ind], y = expl <math>var[[i-1 for i in ind]], c='#ff33
        00')
        for i in ind:
            ax1.annotate(s = "({}, {})".format(i, np.round(expl var[i-1], 2)), xy=(i-1)
         , expl_var[i-1]),
                         xytext = ( i+20, expl var[i-1] - 0.01), fontweight='bold')
        change in expl var = [expl var[i+1] - expl var[i] for i in range(len(expl var)
        -1)]
        ax2.plot(change in expl var)
        ax2.set ylabel("Gain in Var Expl with One Additional LF", fontsize=10)
        ax2.yaxis.set label position("right")
        ax2.set xlabel("# Latent Facors", fontsize=20)
        plt.show()
```

I think 500 dimensions is good enough

- By just taking (20 to 30) latent factors, explained variance that we could get is 20 %.
- To take it to 60%, we have to take almost 400 latent factors. It is not fare.
- It basically is the gain of variance explained, if we add one additional latent factor to it.
- By adding one by one latent factore too it, the **_gain in expained variance** with that addition is decreasing. (Obviously, because they are sorted that way).
- LHS Graph:
 - **x** --- (No of latent factos),
 - y --- (The variance explained by taking x latent factors)
- More decrease in the line (RHS graph) :
 - We are getting more expained variance than before.
- · Less decrease in that line (RHS graph) :
 - We are not getting benifitted from adding latent factor furthur. This is what is shown in the plots.
- RHS Graph:
 - **x** --- (No of latent factors),
 - y --- (Gain n Expl_Var by taking one additional latent factor)

```
In [0]: # Let's project our Original U_M matrix into into 500 Dimensional space...

         print("-"*50)
         print("time:",datetime.now()-start)
```

: This is taking more time for each user than Original one.

- from above plot, It took almost 12.18 for computing similar users for one user
- We have 405041 users with us in training set.
- $405041 \times 12.18 = = = 4933399.38 \,\text{sec} = = = 82223.323 \,\text{min} = = = 1370.388716667 \,\text{hours} = 12.18 \,\text{min} = = = 12.18$
 - Even we run on 4 cores parallelly (a typical system now a days), It will still take almost (14 15) days.
- Why did this happen...??
 - Just think about it. It's not that difficult.

-----get it ??)-----

Is there any other way to compute user user similarity..??

-An alternative is to compute similar users for a particular user, whenenver required (ie., Run time)

- We maintain a binary Vector for users, which tells us whether we already computed or not..
- ***If not*** :
- Compute top (let's just say, 1000) most similar users for this given user, an d add this to our datastructure, so that we can just access it(similar users) without recomputing it again.
- ***If It is already Computed***:
 - Just get it directly from our datastructure, which has that information.
- In production time, We might have to recompute similarities, if it is compute d a long time ago. Because user preferences changes over time. If we could maintain some kind of Timer, which when expires, we have to update it (recompute it).
- ***Which datastructure to use:***
 - It is purely implementation dependant.
 - One simple method is to maintain a **Dictionary Of Dictionaries**.

3.4.2 Computing Movie-Movie Similarity matrix

```
In [25]:
         start = datetime.now()
         if not os.path.isfile('movie_movie_sim_sparse.npz'):
             print("It seems you don't have that file. Computing movie movie similarit
         y...")
             start = datetime.now()

4.3.2 Transforming data for Surprise models

```
In [154]: from surprise import Reader, Dataset
```

4.3.2.1 Transforming train data

- We can't give raw data (movie, user, rating) to train the model in Surprise library.
- They have a saperate format for TRAIN and TEST data, which will be useful for training the models like SVD, KNNBaseLineOnly....etc..,in Surprise.
- We can form the trainset from a file, or from a Pandas DataFrame.
 http://surprise.readthedocs.io/en/stable/getting_started.html#load-dom-dataframe-py.
 (http://surprise.readthedocs.io/en/stable/getting_started.html#load-dom-dataframe-py)

```
In [155]: # It is to specify how to read the dataframe.
# for our dataframe, we don't have to specify anything extra..
reader = Reader(rating_scale=(1,5))

# create the traindata from the dataframe...
train_data = Dataset.load_from_df(reg_train[['user', 'movie', 'rating']], read er)

# build the trainset from traindata.., It is of dataset format from surprise l ibrary..
trainset = train_data.build_full_trainset()
```

4.3.2.2 Transforming test data

Testset is just a list of (user, movie, rating) tuples. (Order in the tuple is impotant)

4.4 Applying Machine Learning models

- Global dictionary that stores rmse and mape for all the models....
 - It stores the metrics in a dictionary of dictionaries

```
keys : model names(string)

value: dict(key : metric, value : value )
```

```
In [157]: models_evaluation_train = dict()
    models_evaluation_test = dict()
    models_evaluation_train, models_evaluation_test
Out[157]: ({}, {})
```

Utility functions for running regression models

```
In [158]: # to get rmse and mape given actual and predicted ratings...
         def get_error_metrics(y_true, y_pred):
             rmse = np.sqrt(np.mean([ (y_true[i] - y_pred[i])**2 for i in range(len(y_p
         red)) ]))
             mape = np.mean(np.abs( (y true - y pred)/y true )) * 100
             return rmse, mape
         def run_xgboost(algo, x_train, y_train, x_test, y_test, verbose=True):
             It will return train results and test results
             # dictionaries for storing train and test results

- SHRINKAGE
 - 2.2 Neighborhood Models in http://courses.ischool.berkeley.edu/i290-dm/s11/SECURE/a1-koren.pdf
 (http://courses.ischool.berkeley.edu/i290-dm/s11/SECURE/a1-koren.pdf)
- predicted Rating : (based on User-User similarity)

$$\hat{r}_{ui} = b_{ui} + rac{\sum\limits_{v \in N_i^k(u)} ext{sim}(u,v) \cdot (r_{vi} - b_{vi})}{\sum\limits_{v \in N_i^k(u)} ext{sim}(u,v)}$$

- b_{ui} Baseline prediction of (user,movie) rating
- $N_i^k(u)$ Set of **K similar** users (neighbours) of **user (u)** who rated **movie(i)**
- sim (u, v) Similarity between users u and v
 - Generally, it will be cosine similarity or Pearson correlation coefficient.
 - But we use shrunk Pearson-baseline correlation coefficient, which is based on the pearsonBaseline similarity (we take base line predictions instead of mean rating of user/item)
- Predicted rating (based on Item Item similarity):

$$\hat{r}_{ui} = b_{ui} + rac{\sum\limits_{j \in N_u^k(i)} \sin(i,j) \cdot (r_{uj} - b_{uj})}{\sum\limits_{j \in N_u^k(j)} \sin(i,j)}$$

Notations follows same as above (user user based predicted rating)

4.4.4.1 Surprise KNNBaseline with user user similarities

```

Conclusion

- According to our ploblem statment Netflix is all about connecting people to the movies they love. To help
 customers find those movies, they developed world-class movie recommendation system: CinematchSM. Its
 job is to predict whether someone will enjoy a movie based on how much they liked or disliked other movies.
 Netflix use those predictions to make personal movie recommendations based on each customer's unique
 tastes.
- Lets Start ->
 - 1. As we know we have dataset which contains MovieIDs range from 1 to 17770 sequentially. CustomerIDs range from 1 to 2649429, with gaps. There are 480189 users.Ratings are on a five star (integral) scale from 1 to 5. Dates have the format YYYY-MM-DD. And as we can see that we have data are in different formate and we need to make it in a format so that we are able apply models on it. And for that what we are doing as we are puting it all the file and merging movies with users and their rating in single dataframe.
 - So after doing all this we will do some EDA on whole dataset, so that we will able to visualise our dataset like distribition of the ratings, what is the avg rating of the movie or avg rating given by the users to the movie and lot more
 - 3. After that we we split our data in train and test which is in ratio of 80:20 and try to to EDA on it. And then we are creating MF of user and movies and make it sparse as we can see our data frame is more than 90% sparse which means very less non zero value in the matrix. and we will do this for our both train and test data set.
 - 4. And then we try Computing Similarity matrices for both user-user similarity and movie-movie similarity but as we can see calculating Similarity_Matrix is not very easy(unless we have huge Computing Power and lots of time) because of number of. users and movies being large.
 - 5. In above points as we have true to compute similarity but it doest works and after we try some other methods like dim reductions and try to compute but unfortunatly it also doest works and as we can see it taking more time and memory than our above method amd the ple is due to dense matrix. so at last what we do we will try to compute similar users for a particular user, whenenver required (ie., Run time) so that at one time we are not going to compte similarity for the whole users/ movies we will do it at run time when ever required for that pertifular user/ movie. And after that we just try to see that it really works or not and we jut got a awsome result. As we can see we have provied a movie id that with movie name Vampire Journals and we got a good result which is similar type movie which we have provied as input.
 - 6. After doing lots of stuff now we will work with different machine learning models and try to compare results of all that and but before that lets first sample our data set because we have lots of data and if we work with all data it will take lots of time so first we will samle our data and then we will introduce with some feature engineering which we are going to use it as a feature on our machine learning models.
 - 7. As we can see in given diagream its shown that in this case study we are using a need lib that is surpise lib with paralell to xgboost models with perform matrix RMSE and MAPE with some hyperparameter tuning on xgboost.
